Exact time-ordered Floquet response: $L = 89$, $A = B = 0.8$, $W = 0$, PBC

Spin-resolved IPR; $D_n = -\ln(\mathrm{IPR}_n)/\ln 89$; shared color scale in each row

Extended static reference $V/t_0 = 0.5$ | Critical static reference $V/t_0 = 2$ | Localized static reference $V/t_0 = 4$

(a) (b) (c)

Mean spin-resolved IPR

(d) (e) (f)

Full-spectrum $\overline{D_n}$

(g) (h) (i)

Outer 20% $\overline{D_n}$

(j) (k) (l)

$\Delta\overline{D_n}$ vs undriven static

φ/π

static limit

Dimensionless ω/t_0

50 true frequency points × 50 distinct phase points per V. The 2 π row copies phase 0 only to close the plot.
ω=0 is the frozen static Hamiltonian, separated by a dotted boundary; outer Floquet D is undefined (gray).
These finite-size participation indicators do not by themselves establish a localization phase transition.
