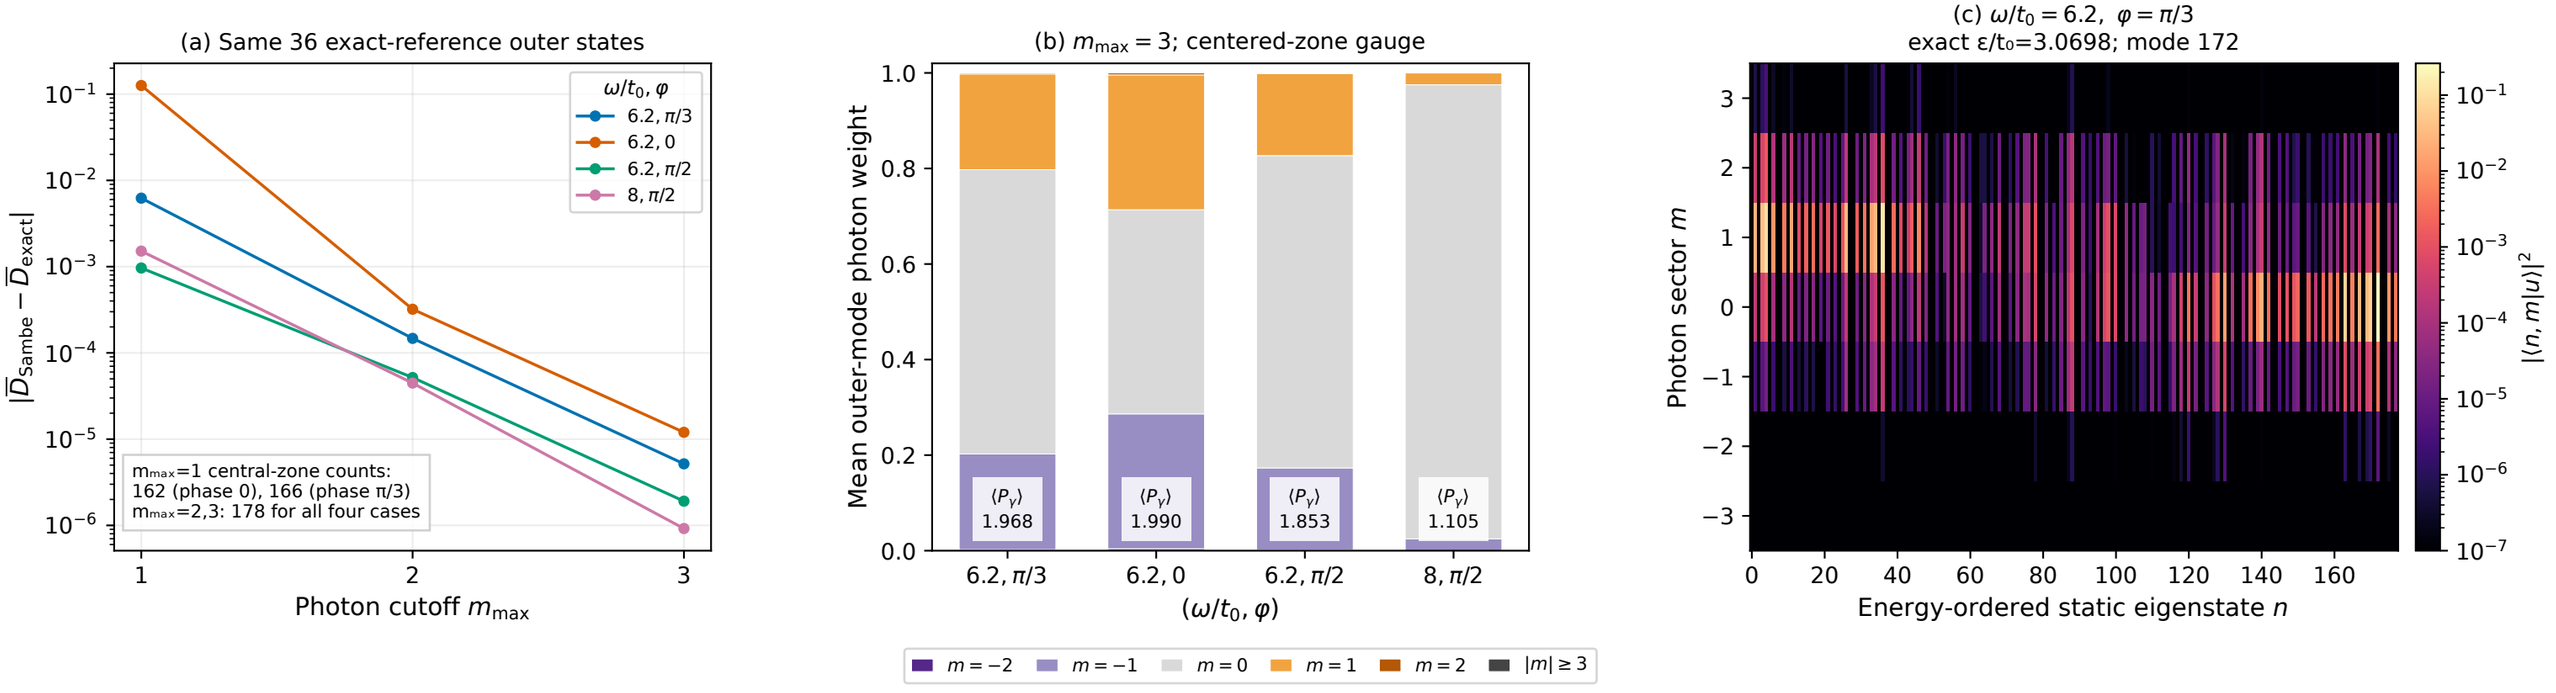
# Floquet–Sambe truncation and multichannel mixing



Exact reference: 178 physical Floquet states; the same highest-|ε| 36 states define each outer comparison. In-zone deficits at photon cutoff 1 are truncation failures; flagged fallback copies are not new bands.

Photon participation is averaged per mode. A folded static state may already occupy m=±1; nonzero sidebands alone do not establish resonance. Panel (c) shows actual static-state/photon coefficients, with color floor $10^{-7}$.

Photon cutoff 3: outer-mean D agrees with exact propagation within $1.2\times10^{-5}$ at these points; reconstructed-wavefunction residuals remain $10^{-5}$–$10^{-4}$, rather than machine precision.
